## Greenhouse Irrigation

### • Objectives:

- Be able to communicate to irrigate plants without overwatering
- Understand how irrigation interacts with porosity in a root substrate

Copyright 2016, Paul Fisher, University of Florida.

2

## Overwatering leads to disease

Overwatering in Ipomea leading to rot

Copyright 2016, Paul Fisher, University of Florida.

3

## Overwatering leads to poor root growth

overwatered

normal

Copyright 2016, Paul Fisher, University of Florida.

4

## Overwatering leads to anaerobic conditions, and poor nutrient uptake

Copyright 2016, Paul Fisher, University of Florida.

5

## However, don't stress your plants by excess drying

wilted once

wilted as liner

normal

Copyright 2016, Paul Fisher, University of Florida.

6

Overwatering causes “leaching”, which is the water, fertilizer and nutrients that flow through the substrate

Copyright 2016, Paul Fisher, University of Florida

7

## Leaching washes out nutrients

- 4500 kg nitrogen/hectare in greenhouse production (Nelson, 2003)

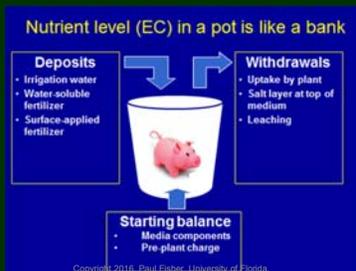

Copyright 2016, Paul Fisher, University of Florida

8

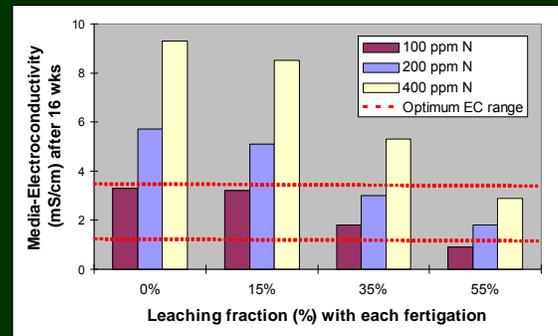

Interpreting EC:  
you move from (a) overhead sprinklers  
to (b) subirrigation or drip.

How will EC in the substrate change?

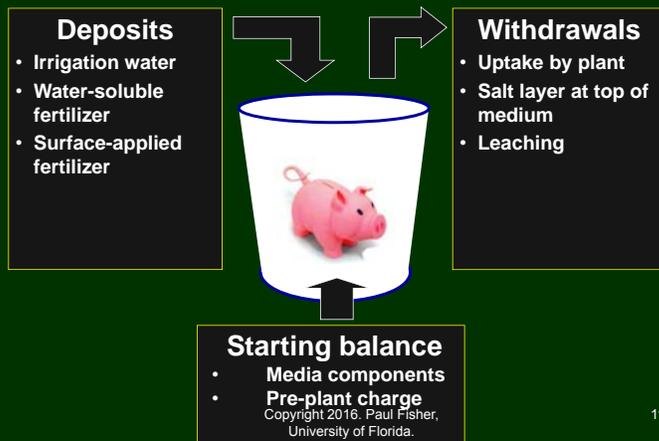

9

Fact: The more you leach (withdraw),  
the more fertilizer you must apply (deposit)

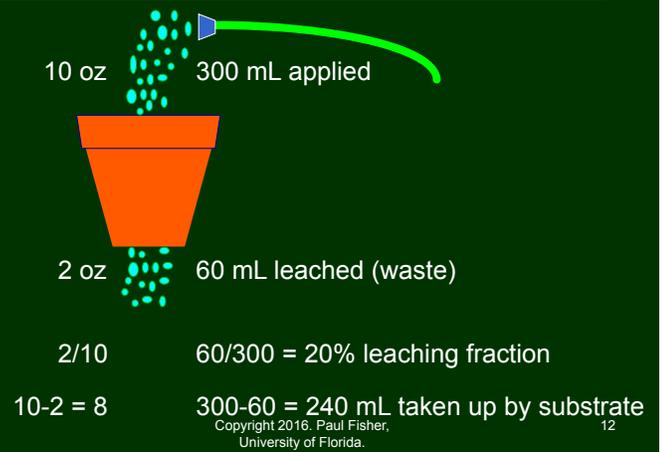

Yelanich and Biernbaum (Michigan State University)

## Nutrient level in a container is like a bank

11

## Calculating leaching fraction

12

## Pros and cons of leaching

Pros	Cons
Evens out non-uniform watering from sprinklers and drippers	Increases fertilizer and water cost
All plants get enough water	Some plants get too much water
Easy to avoid substrate EC increasing over time because salts are washed through	Increases runoff to environment or need to capture and treat
Low management thought/skill required	Increases greenhouse humidity, root diseases

Leaching should only be needed because of:

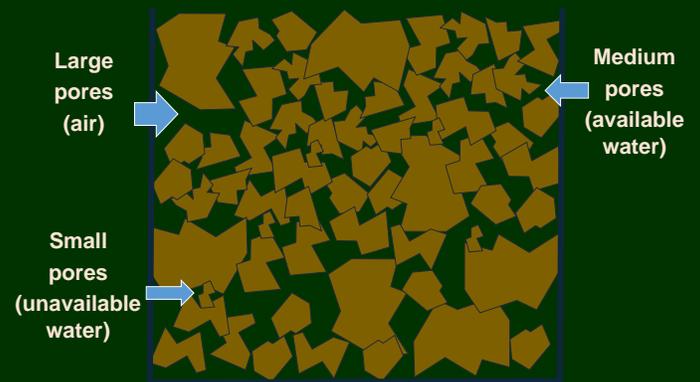

- Rain on uncovered crops
- Uneven drip emitters or sprinklers
- Poor wettability or water holding of substrate
- Removal of sodium & chloride if poor water quality

Leaching because fertilizer and/or water are over-applied is wasteful

Copyright 2016, Paul Fisher, University of Florida.

13

## Irrigation interacts with porosity in substrates

Would field soil make a good container substrate?

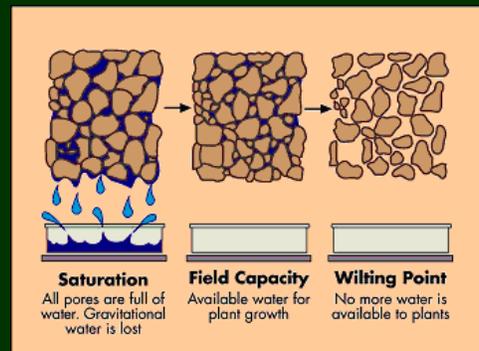

## Porosity in substrates

- Water + Air + Solid + Plant make up the Total Container Volume
- Of these, Water + Air = Porosity
- Water volume after complete irrigation and draining is called "water-holding capacity"
- Water holding/container differs with container size, so it is also called "container capacity"
- We will show how to test porosity in the greenhouse

Copyright 2016, Paul Fisher, University of Florida.

15

## Irrigation interacts with the root substrate - avoid saturation or excess wilting

Copyright 2016, Paul Fisher, University of Florida. [http://www.tankonyvtar.hu/en/tartalom/tamop425/0032\\_talajtan/ch07s02.html](http://www.tankonyvtar.hu/en/tartalom/tamop425/0032_talajtan/ch07s02.html)

## Fine particles have small pores which easily fill with water

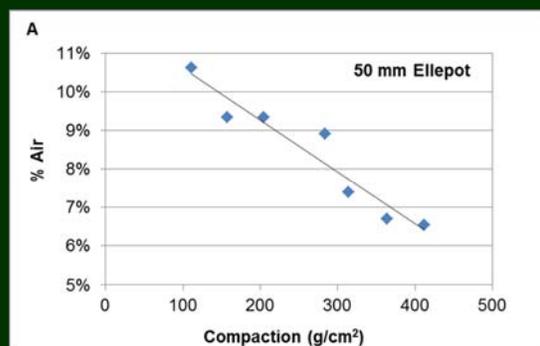

- Water held on particle surface and between particles
- Pores are filled with water or air
- Large particles = less water holding capacity, more air
- Small particles = more water holding capacity, less air

Copyright 2016, Paul Fisher, University of Florida.

17

## Compaction of substrate drives out air

24

## Water content inside a container

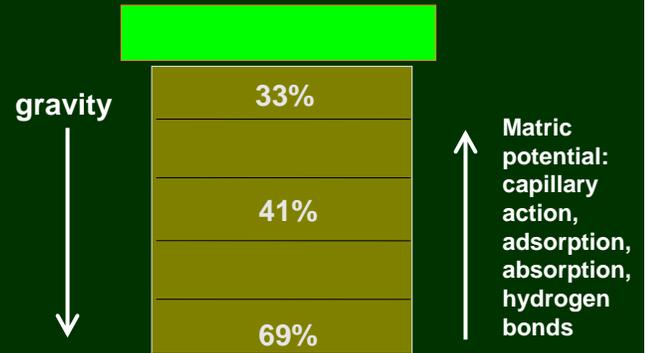

- Water content (% of volume) versus container height.

Copyright 2016, Paul Fisher, University of Florida.

25

## Several forces affect water content

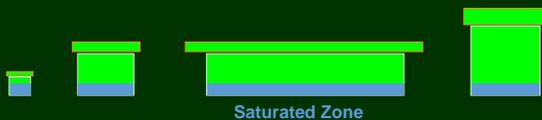

Copyright 2016, Paul Fisher, University of Florida.

26

## The saturated zone

- A container is a "perched water table" - the saturated zone is similar for a given substrate regardless of container height.

Copyright 2016, Paul Fisher, University of Florida.

27

## Size of container is important.

- The proportion of air, water and soil varies with container height.
- These are examples with one peat/perlite substrate:

	288 cell	10-cm pot	15-cm pot
<b>Air (%)</b>	3	13	20
<b>Water (%)</b>	84	74	67
<b>Solid (%)</b>	13	13	13

Copyright 2016, Paul Fisher, University of Florida.

28

## Size of container is important

- It is therefore particularly important to avoid over-watering (lack of aeration) in small container sizes.

Copyright 2016, Paul Fisher, University of Florida.

29

## When & how much to water?

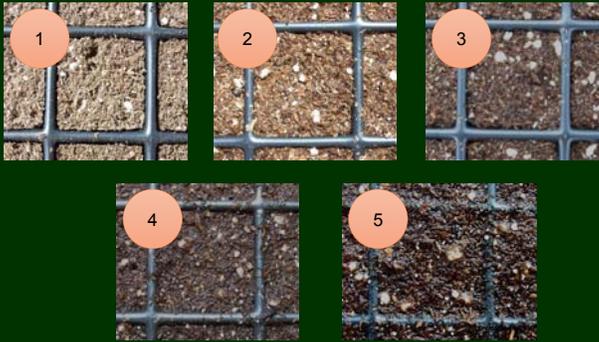

- Observation (1 to 5 moisture scale)
- Target leaching fraction
- Substrate moisture sensors
- Climate-based evapotranspiration modeling

31

## Moisture levels (Ball Tagawa, Colorado)

Level	Class	Sight	Feel	Culture
5	Saturated	Shiny black; standing water. Soaked	Very heavy; media feels soaked and dripping	No oxygen for roots; few seeds germinate; soak
4	Wet	Dark brown; no standing water.	Heavy; can squeeze out moisture when pressed	Maximum acceptable water level
3	Medium	Brown	Average weight; media will feel moist; maybe squeeze out droplets.	Optimum & transitional level
2	Dry	Light brown	Light weight; no free moisture	Typically do not dry below level; wet / dry cycle develops roots
1	Baked	Tan; media may pull away from cell sides	Very light weight; no moisture, almost dusty	Plants desiccate & die rapidly; only cactus survive at this level

Copyright 2016, Paul Fisher, University of Florida

32

## There are other tests of moisture level

Moisture content (water weight/total weight)

Less than 30%

35-45%

50-60%

65-70%

75-80%

## When and how much to water: target leaching fraction

- Typical target 20 - 25% leaching in rock substrate
- Usually much higher in reality

Copyright 2010, Paul Fisher, University of Florida.

37

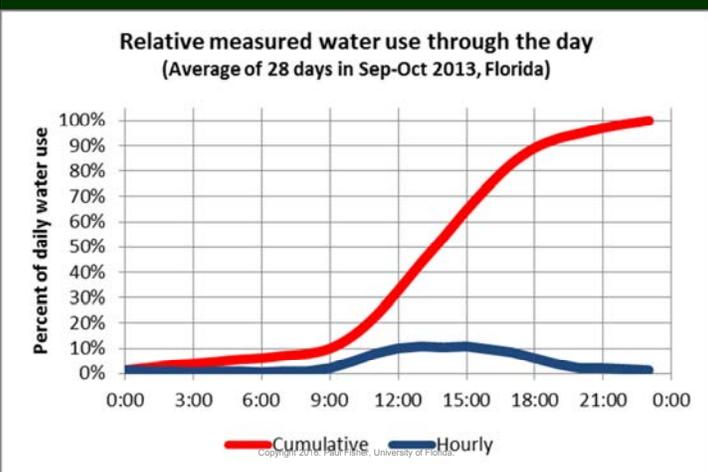

## Substrate moisture level: continuous weight measurement and logging

Copyright 2010, Paul Fisher, University of Florida.

38

## Weight scale shows 80% water lost during daylight hours

Copyright 2010, Paul Fisher, University of Florida.

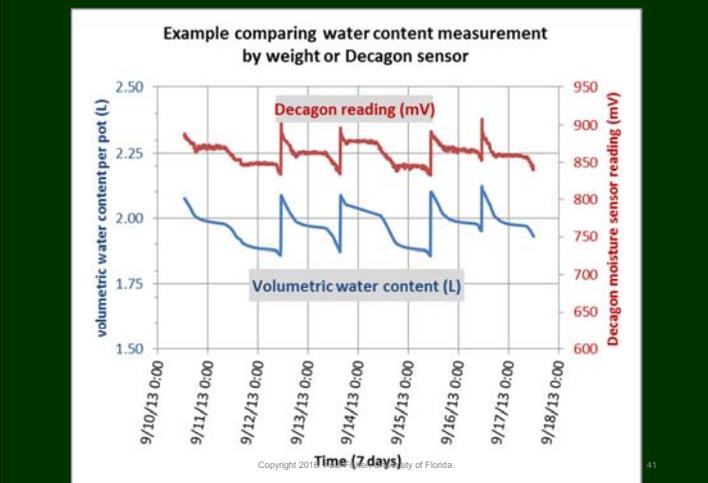

## Substrate moisture level can also be measured with sensors

Copyright 2010, Paul Fisher, University of Florida.

40

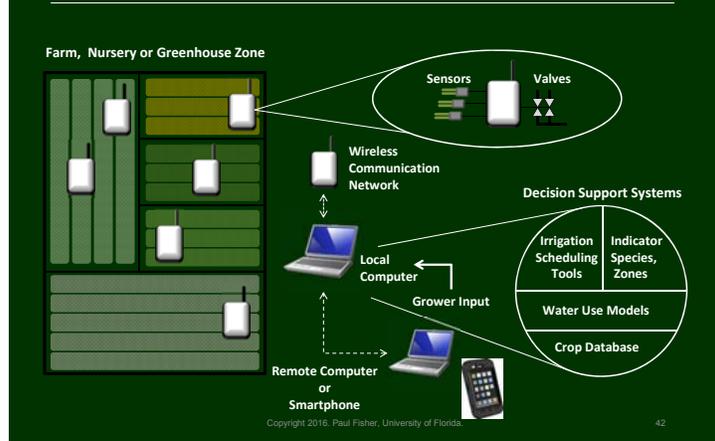

## Moisture level measured by weight or sensor

Copyright 2010, Paul Fisher, University of Florida.

41

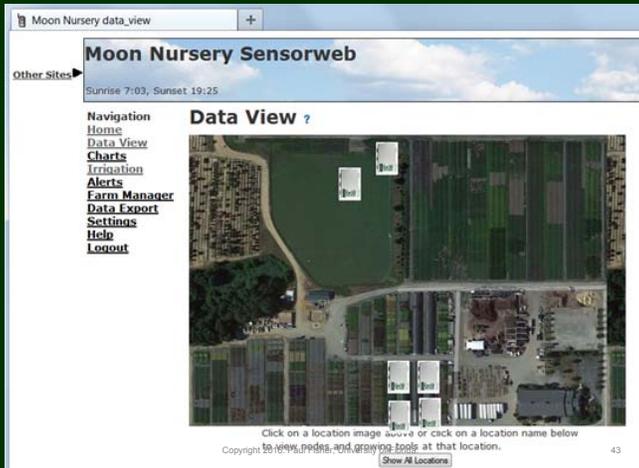

## Real-time data can be accessed from wireless sensor networks (smart-farms.net)

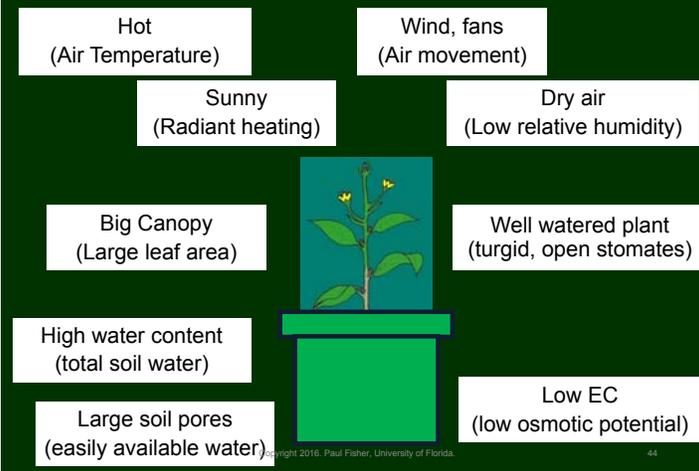

Copyright 2010, Paul Fisher, University of Florida.

42

## Sensor data available on protected website

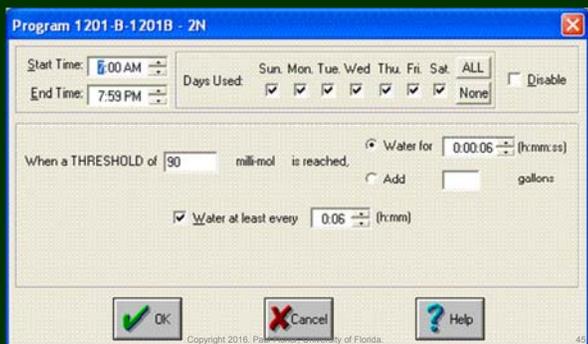

## Water loss (evapotranspiration) can also be modeled

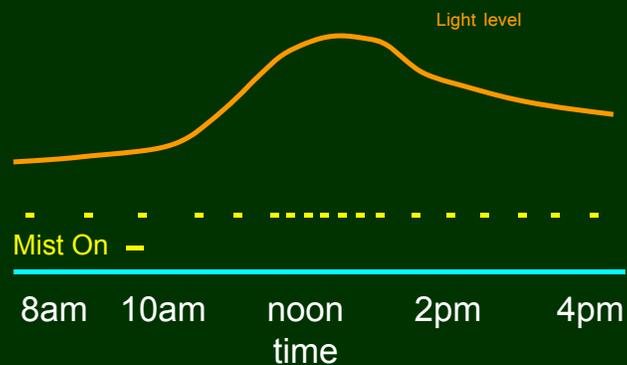

## Climate-based modeling of ET Simple: light accumulation

An example mist setting for propagation

## Mist scheduling with solar units

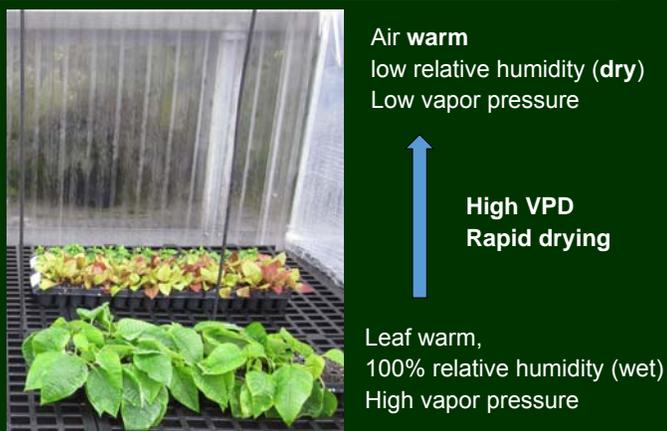

## More growers are now misting based on Vapor Pressure Deficit (VPD)

- VPD = difference between vapor pressure in leaf (at saturation) and vapor pressure in air.
- More useful than relative humidity when modeling evaporation

## More water uptake with warm, dry air

## Less water uptake with cool, wet air

Air cool  
High relative humidity (wet)  
High vapor pressure

Low VPD  
Slow drying

Leaf warm,  
100% relative humidity (wet)  
High vapor pressure

49

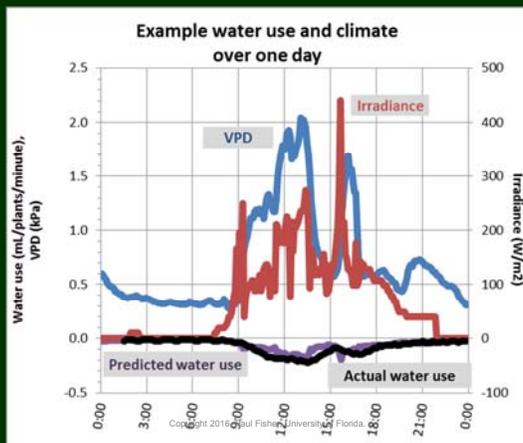

## Climate model-based irrigation: Predicting evapotranspiration with Vapor Pressure Deficit, Irradiance and Leaf Area

Copyright 2018, Paul Fisher, University of Florida.

50

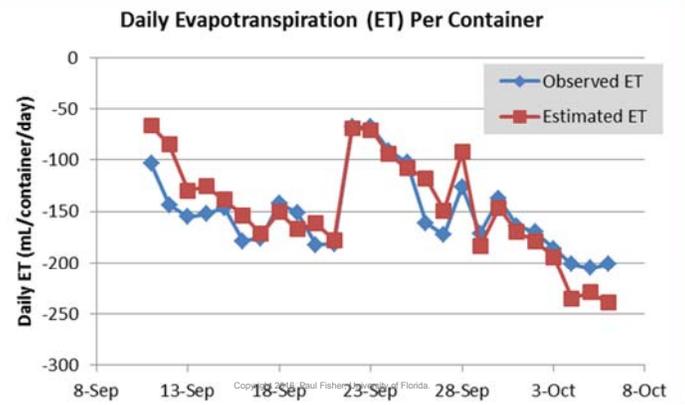

## Hourly water use

Copyright 2018, Paul Fisher, University of Florida.

51

## Daily water use

Copyright 2018, Paul Fisher, University of Florida.

## Climate Modeling to Predict Evapotranspiration (ET)

$$ET = A * (1 - \exp(-0.6 * L)) * \text{Light} + B * L * \text{VPD}$$

- ET = evapotranspiration (water loss)
- A and B are statistical parameters
- L = leaf area index
- Light = irradiance in  $W/m^2$
- VPD = vapor pressure deficit in kPa

- Climate measured with mini weather station
- ET + desired leaching = Volume to apply
